

El algoritmo de Ruffini (Horner) y su generalización para ordenadores.
Aladar Peter Santha

Teorema 1: Si $f(X) = a_n X^n + a_{n-1} X^{n-1} + \dots + a_2 X^2 + a_1 X + a_0$, $a_i \in A$, $a \in A$, son dos polinomios con coeficientes en un anillo conmutativo con elemento neutro, entonces existe un polinomio $q(X) \in A[X]$ de grado $n-1$ y $r \in A$ tales que

$$f(X) = q(X) - a \cdot q(X) + r \quad (1)$$

Demostración: Suponiendo que

$$\begin{aligned} q(X) &= b_{n-1} X^{n-1} + b_{n-2} X^{n-2} + \dots + b_1 X + b_0 \\ (X-a) \cdot q(X) + r &= b_{n-1} X^n + b_{n-2} X^{n-1} + b_{n-3} X^{n-2} + \dots \\ &\dots + b_2 X^3 + b_1 X^2 + b_0 X + r - ab_0 \end{aligned}$$

, de la igualdad (1) resulta que

$$\begin{aligned} b_{n-1} &= a_n \\ b_{n-2} - ab_{n-1} &= a_{n-1} \Leftrightarrow b_{n-2} = a_{n-1} + ab_{n-1} \\ b_{n-3} - ab_{n-2} &= a_{n-2} \Leftrightarrow b_{n-3} = a_{n-2} + ab_{n-2} \\ \dots \\ b_2 - ab_3 &= a_3 \Leftrightarrow b_2 = a_3 + ab_3 \\ b_1 - ab_2 &= a_2 \Leftrightarrow b_1 = a_2 + ab_2 \\ b_0 - ab_1 &= a_1 \Leftrightarrow b_0 = a_1 + ab_1 \\ r - ab_0 &= a_0 \Leftrightarrow r = a_0 + ab_0 \end{aligned} \quad (2)$$

Según las igualdades (2), al conocer el coeficiente b_i del polinomio $q(X)$, el coeficiente b_{i-1} se puede calcular según la fórmula siguiente:

$$b_{i-1} = a_i + ab_i \quad (i = n-1, \dots, 0).$$

Este procedimiento sencillo para el cálculo de los coeficientes del cociente, entre el polinomio $f(X)$ y el polinomio $X - a$, se llama el algoritmo de Ruffini (o Horner). El cálculo se puede organizar según el esquema siguiente:

	a_n	a_{n-1}	a_{n-2}	...	a_2	a_1	a_0
a		ab_{n-1}	ab_{n-2}	...	ab_2	ab_1	ab_0
	$b_{n-1} = a_n$	b_{n-2}	b_{n-3}	...	b_1	b_0	r

Para llenar la tabla, se completan primero las casillas con los coeficientes del polinomio y la casilla con el valor de a . Como segundo paso, en la casilla que se encuentra en la columna de a_n y la tercera fila, se coloca el valor de a_n . En la tercera etapa, se llenan progresivamente las casillas de la segunda y la tercera fila. Para esto se multiplica con a el contenido de la última casilla rellenada en la tercera fila y se coloca el producto en la casilla de la segunda fila de la columna siguiente, luego se suma el contenido de ésta última casilla con el contenido de la casilla que se encuentra en la primera fila de la misma columna, colocando la suma en la tercera fila de ésta columna. El proceso se continúa hasta que la tabla quedará rellena da.

Ejemplo 1: Si $A = R$, $f(X) = X^4 - 2X^2 + 2X + 5$ y $a = 2$, entonces se obtiene la tabla siguiente:

	1	0	-2	3	-5
2		2	4	4	14
	1	2	2	7	11

, de donde resulta que

$$q(x) = X^3 + 2X^2 + 2X + 7 \quad y \quad r = 11.$$

Si los coeficientes del polinomio y el valor del parámetro a son enteros o decimales, la codificación del cálculo del ejemplo 1 es la siguiente:

```

Public Function RuffiniAR(ByRef p() As Double, ByVal a As Double) As String
    Dim q() As Double, g As Integer, i As Integer
    Dim res As String, c() As Double, rc As String
    g = UBound(p()): rc = Chr$(13) + Chr$(10)
    ReDim q(g), c(g - 1)
    q(0) = p(0)
    For i = 0 To g - 1
        q(i + 1) = q(i) * a + p(i + 1)
    Next i
    For i = 0 To g - 1: c(i) = q(i): Next i      'c() es el cociente
    res = "Cociente = " + FormatoPolR(c()) + rc
    RuffiniAR = res + "Resto = " + Str$(q(g)) ' q(g) es el resto
End Function

' -----
Public Function FormatoPolR(ByRef qx() As Double) As String
    Dim i As Integer, pol As String
    gx = UBound(qx())
    If Abs(qx(0)) = 1 Then
        If qx(0) = 1 Then
            If gx > 1 Then
                pol = pol + "X^" + Str$(gx)
            Else
                pol = pol + "X"
            End If
        End If
        If qx(0) = -1 Then
            If gx > 1 Then
                pol = pol + "- X^" + Str$(gx)
            Else
                pol = pol + "- X"
            End If
        End If
    Else
        If Abs(qx(0)) > 1 Then
            pol = pol + Str$(qx(0))
        Else
            If qx(0) > 0 Then
                pol = pol + "0" + Mid$(Str$(Abs(qx(0))), 2)
            Else
                pol = pol + "- 0" + Mid$(Str$(Abs(qx(0))), 2)
            End If
        End If
        If gx > 1 Then
            pol = pol + " X^" + Str$(gx)
        Else
            pol = pol + " X"
        End If
    End If
    For i = 1 To gx
        If qx(i) <> 0 Then
            If qx(i) < 0 Then
                pol = pol + " - "
            Else
                pol = pol + " + "
            End If
            If Abs(qx(i)) <> 1 Then
                If Abs(qx(i)) > 1 Then
                    pol = pol + Mid$(Str$(Abs(qx(i))), 2)
                Else
                    pol = pol + Str$(Abs(qx(i)))
                End If
            End If
        End If
    Next i
End Function

```

```

        Else
            pol = pol + "0" + Mid$(Str$(Abs(qx(i))), 2)
        End If
    Else
        If i = gx Then
            pol = pol + Mid$(Str$(1), 2)
        End If
    End If
    If i < gx Then
        pol = pol + " X"
    End If
    If i < gx - 1 Then
        pol = pol + "^" + Str$(gx - i)
    End If
End If
Next i
VerPolR = pol
End Function

```

Observación 1: Si se pone $X = a$ en la igualdad (1) resulta que $f(X) = r$, es decir el valor del polinomio $f(X)$ en el punto a es el resto de la división del polinomio con $X - a$. De hecho, el esquema de Ruffini se utiliza más bien para calcular los valores de las funciones de tipo polinomio (este es el caso cuando se aproximan los ceros de un polinomio por el método de la bipartición). La función *RuffiniAR* se puede adaptar a este caso, cuando no interesan los coeficientes del cociente:

```

Public Function ValPolR(ByRef p() As Double, ByVal a As Double) As Double
    Dim i As Integer, gp As Integer, q As Double
    gp = UBound(p()): q = p(0)
    For i = 0 To gp - 1: q = q * a + p(i + 1): Next i
    ValPolR = q
End Function

```

Si el polinomio o el parámetro a tienen valores que no son ni enteros ni decimales, entonces considerando valores aproximados para ellos, el código *RuffiniA* devolverá un resultado que es también aproximado. Por ejemplo, si

$$f(X) = X^4 + \sqrt{3}X^2 - 2X^2 + 2X + 5 \text{ y } a = 7/3$$

Entonces considerando las aproximaciones $\sqrt{3} \approx 1.732050807588$ y $7/3 \approx 2.333333333333$, la función *RuffiniA* devolverá el resultado siguiente:

$$q(X) = X^3 + q_1 X^2 + q_2 X + q_3 \text{ y } r \approx 50.4232133\dots$$

, donde $q_1 \neq 4.065384140901$, $q_2 \approx 7.48589632876764$ y $q_3 \approx 4670914337887$.

La precisión de estos últimos cálculos no es muy grande, teniendo en cuenta que haciendo los cálculos a mano se obtiene $r = 50.42319\dots$.

Si en la resolución de las ecuaciones algebraicas por el método de la bipartición se quieren calcular los ceros con más de 16 decimales después del punto decimal, los valores de la polinomio hay que calcular con el método de Ruffini adaptado a las operaciones con enteros y decimales largos:

```

Public Function ValPolRG(ByRef p() As String, ByVal a As String) As String
    Dim i As Integer, gp As Integer, q As String, x(2) As String, n As Integer
    gp = UBound(p()): q = p(0): n = 7
    For i = 0 To gp - 1
        x(1) = q: x(2) = a: x(1) = MultiplicarDec(x(1), x(2))
        x(2) = p(i + 1): q = SumarDec(x(1), x(2))
    Next i
    ValPolRG = q
End Function

```

Ejemplo 2: Si $A = C$, $f(X) = -3iX^4 - 2X^2 + 6 + iX + 7 - 4i$ y $a = 3 + i$, entonces se obtiene la tabla siguiente:

	2-3i	0	-2	5+i	7-4i
3+i		9-7i	34-12i	108-4i	342+104i
	2-3i	9-7i	32-12i	113-3i	349+100i

Así,

$$q(X) = -3iX^3 + (-7i)X^2 + (2-12i)X + 113-3i \quad r = 349+100i$$

Los cálculos se pueden programar para ordenadores de la manera siguiente:

```

Public Function RuffiniAC(ByRef p1() As Double, ByRef p2() As Double, ByRef a() As Double) As Variant
    Dim i As Integer, gx As Integer, cocci As String, r As String, rc As String
    Dim q() As Double, x() As Double, rt() As Double, ra As String
    gx = UBound(p1()): rc = Chr$(13) + Chr$(10)
    ReDim q(gx, 2), x(2)
    q(0, 1) = p1(0): q(0, 2) = p2(0)
    For i = 1 To gx
        x(1) = q(i - 1, 1): x(2) = q(i - 1, 2)
        rt() = ProdNC(x(), a())
        q(i, 1) = rt(1) + p1(i): q(i, 2) = rt(2) + p2(i)
    Next i
    ReDim q1(gx - 1), q2(gx - 1)

```

Ejemplo 3: Sea $A = DU$, donde DU es el anillo de los números duales, que tienen la forma $a + b\varepsilon$ ($a, b \in R$, $\varepsilon^2 = 0$ y $\varepsilon \neq 0$). Si

$f(X) = -3\varepsilon X^4 - 2X^2 + 6 + \varepsilon X + 7 - 4\varepsilon$ y $a = 3 + \varepsilon$
, entonces

	$2-3\varepsilon$	0	-2	$5+\varepsilon$	$7-4\varepsilon$
$3 + \varepsilon$		$6-7\varepsilon$	$18-15\varepsilon$	$48-29\varepsilon$	$159-31\varepsilon$
	$2-3\varepsilon$	$6-7\varepsilon$	$16-15\varepsilon$	$53-28\varepsilon$	$166-35\varepsilon$

$q(X) = -3\varepsilon X^3 + 6 - 7\varepsilon X^2 + 6 - 15\varepsilon X + 53 - 28i$ y $r = 166 - 35\varepsilon$
Los cálculos se pueden programar para ordenadores de la manera siguiente:

```

Public Function RuffiniAD(ByRef p1() As Double, ByRef p2() As Double, ByRef a() As Double) As Variant

Si en lugar de $X-a$, se desea dividir el polinomio $f(X)$ con el polinomio $bX-a$ ($b \neq 0$), entonces de las igualdades:

$$f(X) = \left(X - \frac{a}{b} \right) \cdot q(X) + r$$

$$f(X) = (X-a)q(X) + r_1$$

$$\left(X - \frac{a}{b} \right) \cdot q(X) + r = (X-a)q(X) + r$$

, resulta que

$$q_1(X) = \frac{q(X)}{b} \quad y \quad r_1 = r$$

Ejemplo 4: Para dividir el polinomio del ejemplo 1 con $3X-2$ se dividirá primero el polinomio $f(X)$ con $X-2/3$. Los cálculos se reflejan en la tabla siguiente:

	1	0	-2	3	-5
$\frac{2}{3}$		$\frac{2}{3}$	$\frac{4}{9}$	$-\frac{28}{27}$	$\frac{106}{81}$
	1	$\frac{2}{3}$	$-\frac{14}{9}$	$\frac{53}{27}$	$-\frac{299}{81}$

, de donde resulta que el cociente y el resto en la división con $3X-2$ son:

$$q(X) = \frac{1}{3}X^3 + \frac{2}{9}X^2 - \frac{14}{27}X + \frac{53}{81} \quad y \quad r = -\frac{299}{81}$$

, respectivamente.

Ejemplo 5: Para dividir el polinomio del ejemplo 2 con $(3-i)X-(2+5i)$ se dividirá el polinomio primero entre $X - \frac{2+5i}{3-i} = X - \left(\frac{1}{10} + \frac{17}{10}i \right)$, según la tabla siguiente:

	$2+3i$	0	-2	$5+i$	$7-4i$
$\frac{1+17i}{10}$		$\frac{-49+37i}{10}$	$\frac{339-398i}{50}$	$-\frac{28}{27}$	$\frac{106}{81}$
	$2+3i$	$\frac{-49+37i}{10}$	$\frac{239-398i}{50}$	$\frac{53}{27}$	$-\frac{299}{81}$

$$q(X) = \frac{3+11i}{10}X^3 + \frac{92+31i}{10}X^2 + \frac{223-191i}{100}X + \frac{159+53i}{270} \quad y \quad r = -\frac{299}{81}$$

Dados el polinomio $P(X)$ de grado n y el número real a , el esquema de Ruffini es también útil para hallar los coeficientes de un polinomio $Q(X)$ de grado n , tal que $Q(X-a) = P(X)$. En efecto, si

$$\begin{aligned} P(X) &= P_1(X-a) + r_0 \\ P_1(X) &= P_2(X-a) + r_1 \\ &\dots \\ P_{n-1}(X) &= P_n(X-a) + r_n \end{aligned}$$

, donde $\text{grado } P_i(X) = n-i \quad i=1, \dots, n$

Entonces

$$\begin{aligned} P(X) &= P_1(X-a) + r_0 \\ &= P_2(X-a) + r_1(X-a) + r_0 \\ &= P_3(X-a) + r_2(X-a) + r_1(X-a) + r_0 \\ &\dots \\ &= r_n(X-a) + r_{n-1}(X-a)^{n-1} + \dots + r_1(X-a) + r_0 \end{aligned}$$

, donde $r_0 = P(a), r_1 = P_1(a), r_2 = P_2(a), \dots, r_n = P_n(a)$.

Los cálculos anteriores se pueden codificar de la manera siguiente:

```
Public Function RuffiniB(ByRef p() As Double, ByVal a As Double) As String
    Dim i As Integer, j As Integer, g As Integer, r() As Double, q() As Double
    g = UBound(p())
    ReDim r(g, g), q(g)
    For i = 0 To g
        r(i, 0) = p(i)
    Next i
    For i = 1 To g
        r(0, i) = p(0)
    Next i
    For j = 1 To g-j
        For i = 1 To g - j + 1
            r(i, j) = a * r(i - 1, j) + r(i, j - 1)
        Next i
    Next j
    q(0) = p(0)
    For i = 1 To g
        q(i) = r(i, g - i + 1)
    Next i
    RuffiniB = FormatoPol(q())
End Function
```

Los coeficientes del polinomio buscado serán los números $q_i \quad i=0, \dots, g$, donde g es el grado del polinomio $p()$.

Ejemplo 6: Si $P(X) = 2X^3 - 7X^2 + 5X + 9$ y $a = 3$ entonces según la función anterior, $Q(X) = 2X^3 + 11X^2 + 17X + 15$ y así, $P(X) = 2(X-3)^3 + 11(X-3)^2 + 17(X-3) + 15$.

Los cálculos a mano se podrían organizar según la tabla siguiente:

	2,	-7	5	9
3	2	-1	2	$15 = r_0$
3	2	5	$17 = r_1$	
3	2	$11 = r_2$		

	$2 = r_3$			
--	-----------	--	--	--

Ejemplo 7: Si $P(X) = X^4 + 3iX^3 + (-7i)X^2 + (1+5i)X + (-i) + 4 + 3i$ y $a = 3 - i$, entonces

$$Q(X) = X^4 + 3iX^3 + (-7+21i)X^2 + (101+11i)X + (26-167i)X + 309 - 282i$$

, y

$$P(X) = (X^4 + 3iX^3 + (-7+21i)X^2 + (101+11i)X + (26-167i)X + 309 - 282i)$$

El esquema de Ruffini para dividir un polinomio por el polinomio $X - a$ se puede generalizar para el caso cuando se divide con un polinomio cuyo coeficiente director es 1. En efecto, si se quiere dividir el polinomio

$$A(X) = a_0X^n + a_1X^{n-1} + \dots + a_{n-1}X + a_n \quad (3)$$

, con el polinomio

$$P(X) = X^m + p_1X^{m-1} + \dots + p_{m-1}X + p_m \quad (m \leq n) \quad (4)$$

, sean

$$Q(X) = q_0X^{n-m} + q_1X^{n-m-1} + \dots + q_{n-m-1}X + q_{n-m} \quad (5)$$

$$R(X) = r_0X^{n-m-1} + r_1X^{n-m-2} + \dots + r_{n-m-2}X + r_{n-m-1} \quad (6)$$

, el cociente y el resto de la división, respectivamente. Entonces se cumple la igualdad

$$A(X) = P(X)Q(X) + R(X) \quad (7)$$

A continuación se efectuará el desarrollo de la expresión $P(X)Q(X) + R(X)$ en los dos casos siguientes:

1) Si $n = 8$ y $m = 3$, el cálculo de la expresión mencionada se puede organizar según la tabla siguiente:

X^8	X^7	X^6	X^5	X^4	X^3	X^2	X^1	X^0
q_0	q_1	q_2	q_3	q_4	q_5			
	p_1q_0	p_1q_1	p_1q_2	p_1q_3	p_1q_4	p_1q_5		
		p_2q_0	p_2q_1	p_2q_2	p_2q_3	p_2q_4	p_2q_5	
			p_3q_0	p_3q_1	p_3q_2	p_3q_3	p_3q_4	p_3q_5
						r_0	r_1	r_2

Así

$$P(X)Q(X) + R(X) = s_0X^8 + s_1X^7 + s_2X^6 + s_3X^5 + s_4X^4 + s_5X^3 + s_6X^2 + s_7X + s_8$$

, donde

$$\begin{aligned} s_0 &= q_0 \\ s_1 &= q_1 + p_1q_0 \\ s_2 &= q_2 + p_1q_1 + p_2q_0 \\ s_3 &= q_3 + p_1q_2 + p_2q_1 + p_3q_0 \\ s_4 &= q_4 + p_1q_3 + p_2q_2 + p_3q_1 \end{aligned} \quad (8)$$

$$\begin{aligned}
s_5 &= a_{q5} + p_1q_4 + p_2q_3 + p_3q_2 \\
s_6 &= p_1q_5 + p_2q_4 + p_3q_3 + r_0 \\
s_7 &= p_2q_5 + p_3q_4 + r_1 \\
s_8 &= p_3q_5 + r_2
\end{aligned}$$

Identificando los polinomios $A \overbrace{X}^{\wedge}$ y $S \overbrace{X}^{\wedge}$ resulta que

$$\begin{aligned}
q_0 &= a_0 \\
q_1 &= a_1 - p_1q_0 = a_1 - \sum_{j+k=1} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k < 1) \\
q_2 &= a_2 - p_1q_1 - p_2q_0 = a_2 - \sum_{j+k=2} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k < 2) \\
q_3 &= a_3 - p_1q_2 - p_2q_1 - p_3q_0 = a_3 - \sum_{j+k=3} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k < 3) \\
q_4 &= a_4 - p_1q_3 - p_2q_2 - p_3q_1 = a_4 - \sum_{j+k=4} p_j \cdot q_k \quad (0 < j \leq m, \quad k < 4) \\
q_5 &= a_5 - p_1q_4 - p_2q_3 - p_3q_2 \quad \Leftrightarrow \quad q_{n-n} = a_{n-m} - \sum_{j+k=n-m} p_j \cdot q_k \quad (0 < j \leq m, \quad k < 5) \\
r_0 &= a_6 - p_1q_5 - p_2q_4 - p_3q_3 = a_{n-m+1} - \sum_{j+k=n-m+1} p_j \cdot q_k \quad (0 < j \leq m, \quad k \leq n-m) \\
r_1 &= a_7 - p_2q_5 - p_3q_4 = a_{n-m+2} - \sum_{j+k=n-m+2} p_j \cdot q_k \quad (0 < j \leq m, \quad k \leq n-m) \\
r_2 &= a_8 - p_3q_5 = a_{n-m+3} - \sum_{j+k=n-m+3} p_j \cdot q_k \quad (0 < j \leq m, \quad k \leq n-m)
\end{aligned} \tag{9}$$

2) Si $n = 8$ y $m = 6$, el cálculo de la expresión $P \overbrace{X}^{\wedge} Q \overbrace{X}^{\wedge} R \overbrace{X}^{\wedge}$ se puede efectuar según la tabla siguiente:

X^8	X^7	X^6	X^5	X^4	X^3	X^2	X^1	X^0
q_0	q_1	q_2						
	p_1q_0	p_1q_1	p_1q_2					
		p_2q_0	p_2q_1	p_2q_2				
			p_3q_0	p_3q_1	p_3q_2			
				p_4q_0	p_4q_1	p_4q_2		
					p_5q_0	p_5q_1	p_5q_2	
						p_6q_0	p_6q_1	p_6q_2
			r_0	r_1	r_2	r_3	r_4	r_5

Así,

$$P \overbrace{X}^{\wedge} Q \overbrace{X}^{\wedge} R \overbrace{X}^{\wedge} = S \overbrace{X}^{\wedge} = s_0 X^8 + s_1 X^7 + s_2 X^6 + s_3 X^5 + s_4 X^4 + s_5 X^3 + s_6 X^2 + s_7 X + s_8$$

$$\begin{aligned}
s_0 &= q_0 \\
s_1 &= q_1 + p_1q_0 \\
s_2 &= q_2 + p_1q_1 + p_2q_0 \\
s_3 &= p_1q_2 + p_2q_1 + p_3q_0 + r_0 \\
s_4 &= p_2q_2 + p_3q_1 + p_4q_0 + r_1 \\
s_5 &= p_3q_2 + p_4q_1 + p_5q_0 + r_2
\end{aligned} \tag{8'}$$

$$\begin{aligned}s_6 &= p_4q_2 + p_5q_1 + p_6q_0 + r_3 \\s_7 &= p_5q_2 + p_6q_1 + r_4 \\s_8 &= p_6q_2 + r_5\end{aligned}$$

Luego, Identificando los polinomios $A(X)$ y $S(X)$ resulta que

$$\begin{aligned}q_0 &= a_0 \\q_1 &= a_1 - p_1q_0 = a_1 - \sum_{j+k=1} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k < 1) \\q_2 &= a_2 - p_1q_1 - p_2q_0 = a_2 - \sum_{j+k=2} p_j \cdot q_k \quad (0 < j \leq 3, \quad 0 \leq k < 2) \\r_0 &= a_3 - p_1q_2 - p_2q_1 - p_3q_0 = a_{n-m+1} - \sum_{j+k=n-m+1} p_j q_k \quad (0 < j \leq m, \quad 0 \leq k \leq n-m) \\r_1 &= a_4 - p_2q_2 - p_3q_1 - p_4q_0 = a_{n-m+2} - \sum_{j+k=n-m+2} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k \leq n-m) \\r_2 &= a_5 - p_3q_2 - p_4q_1 - p_5q_0 = a_{n-m+3} - \sum_{j+k=n-m+3} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k \leq n-m) \\r_3 &= a_6 - p_4q_2 - p_5q_1 - p_6q_0 = a_{n-m+4} - \sum_{j+k=n-m+4} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k \leq n-m) \\r_4 &= a_7 - p_5q_2 - p_6q_1 = a_{n-m+5} - \sum_{j+k=n-m+5} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k \leq n-m) \\r_5 &= a_8 - p_6q_2 = a_{n-m+6} - \sum_{j+k=n-m+6} p_j \cdot q_k \quad (0 < j \leq m, \quad 0 \leq k \leq n-m)\end{aligned}\tag{9'}$$

Examinando los dos casos anteriores se puede enunciar el teorema siguiente:

Teorema 2: Dados los polinomios $A(X)$ y $P(X)$, las fórmulas que determinan los polinomios $Q(X)$ y $R(X)$ y que verifican en la igualdad (7) son las siguientes:

$$q_0 = a_0 \quad y \quad q_i = a_i - \sum_{j+k=i} p_j \cdot q_k, \quad 0 < i \leq n-m, \quad 0 < j \leq m, \quad 0 \leq k < i \tag{10}$$

$$r_i = a_{n-m+i+1} - \sum_{j+k=n-m+i+1} p_j \cdot q_k, \quad 0 \leq i \leq m-1, \quad 0 < j \leq m, \quad 0 \leq k \leq n-m \tag{11}$$

Por supuesto, las fórmulas (10) y (11) no son tan manejables como las fórmulas en el caso de la división entre $X - a$, pero son fácilmente programables y el ordenador las ejecuta con tanta facilidad como las personas la regla normal de Ruffini.

Esta manera de efectuar la división tiene sus ventajas, sobre todo cuando los coeficientes de los polinomios son enteros o decimales (trabajar con fracciones es más penoso). Si el coeficiente director p_0 del polinomio $P(X)$ no fuera 1 entonces habrá que dividir $P(X)$ entre p_0 y hacer la división con el polinomio así obtenido. El resto será válido y para obtener el verdadero cociente hay que dividir el cociente obtenido entre p_0 .

Ejemplo 3: De acuerdo con lo dicho anteriormente, para hallar el cociente y el resto en la división euclídea del polinomio $A(X)$ entre $P(X)$, donde

$$A(X) = 2X^8 - 3X^7 + 5X^6 - X^5 + 3X^4 + 4X^3 - 7X^2 + 3X - 4$$

$$P(X) = X^4 - 2X^3 + 5X^2 + 3X - 4$$

, se obtiene el cociente y el resto siguientes:

$$Q(X) = 2X^4 + X^3 - 3X^2 - 18X - 13$$

$$R(X) = 81X^3 + 100X^2 - 30X - 56$$

, respectivamente.

Para dividir el polinomio $A(X)$ entre el polinomio $P(X)$, cuyo coeficiente director $b_0 \neq 1$, se dividirá el polinomio $A(X)$ entre el polinomio

$$P_1(X) = \frac{1}{p_0} P(X)$$

, según el esquema general de Ruffini. Suponiendo que,

$$A(X) = P(X) \cdot Q(X) + R(X)$$

, de

$$A(X) = \frac{1}{p_0} P(X) \cdot Q_1(X) + R_1(X)$$

, resulta que

$$Q(X) = \frac{1}{p_0} Q_1(X) \quad y \quad R(X) = R_1(X)$$

En general, los coeficientes del cociente y del resto serán aproximaciones decimales de los coeficientes reales.

Ejemplo 4: Para dividir el polinomio

$$A(X) = 3X^5 - 7X^3 + 4X^2 - 5X + 12$$

, con el polinomio

$$P(X) = 2X^3 - 5X^2 + 7X - 8$$

, se divide primero el polinomio $A(X)$ entre el polinomio

$$P_1(X) = X^3 - 2.5X^2 + 3.5X - 4$$

, y se obtiene el cociente y el resto

$$Q_1(X) = 3X^2 + 7.5X - 4 \quad y \quad R_1(X) = -7.125X^2 + 20.625X + 17$$

, respectivamente. Entonces el cociente y el resto de la división inicial serán:

$$Q(X) = \frac{1}{2} Q_1(X) = 1.5X^2 + 3.75X - 2 \quad y \quad R(X) = R_1(X)$$

, respectivamente.

Ejemplo 5: Para dividir el polinomio

$$A(X) = 3X^5 - 7X^3 + 4X^2 - 5X + 12$$

, entre el polinomio

$$P(X) = 7X^3 - 5X^2 + 7X - 8$$

, hay que dividir el polinomio $P(X)$ entre 7 y así los coeficientes del polinomio $P_1(X)$ ya no serán números decimales sino números reales periódicos.

Por tanto, si no se quiere trabajar con fracciones, tendremos que hacer la división de $A(X)$ con un polinomio $P_2(X)$ que, al trabajar con bastantes decimales después de la coma, será una buena aproximación del polinomio $P_1(X)$. Así el resultado final será también una aproximación del cociente verdadero. Tomando

$$P_2(X) = X^3 - 0.714286X^2 + X - 1.142857$$

, se obtendrá el resultado aproximado siguiente;

$$Q(X) \approx 0.428572X^2 + 0.306123X - 1.209912$$

$$R(X) \approx -0.763851X^2 + 5.918367X + 2.320702$$

Para efectuar la división de esta manera, se pueden utilizar las funciones siguientes:

```
Public Function RuffiniG(ByRef a() As Double, ByRef p() As Double) As Variant
    Dim i As Integer, j As Integer, k As Integer, r() As Double, q() As Double
    Dim r1() As Double, p1() As Double, gr As Integer, sw As Integer
    Dim j1 As Integer, ga As Integer, gp As Integer, gb As Integer
    Dim cxq As String, cxr As String, res(2) As String
    ga = UBound(a()): gp = UBound(p()): gb = ga - gp
```

```

ReDim b(gb), p1(gp)
If p(0) <> 1 Then

        Else
            pol = pol + " - " + Mid$(Str$(Abs(x(0))), 2)
        End If
    End If
    End If
    VerPol = pol
End Function

```

Ejemplo 6: Según el código anterior, si

$A \triangleq 4X^6 - 7X^5 + 8X^4 + 3X^3 - 12X^2 + 5X + 4$ y $P \triangleq X^5 - 2X^4 + 3X^3 + 5X^2 - X + 4$, entonces $Q \triangleq 4X + 1$ y $R \triangleq -2X^4 - 20X^3 - 13X^2 - 10X$.

Ejemplo 7: Si $A \triangleq 4X^6 - 7X^5 + 8X^4 + 3X^3 - 12X^2 + 5X + 4$ y $P \triangleq 5X^3 + 4X^2 - 3X + 7$, entonces $Q \triangleq 0.8X^3 - 2.04X^2 + 3.712X - 4.7136$ y $R \triangleq 32.2704X^2 - 35.1248X + 36.9952$

Ejemplo 8: si $A \triangleq 7X^4 - 4X^3 + 15X^2 - 3X + 7$ y $P \triangleq 3X^2 - 11X + 5$, entonces el ordenador devuelve el resultado siguiente:

$$Q \triangleq 2.333333333333X^2 + 7.222222222222X + 27.5925925925926X^2 \\ R \triangleq 264.407407407407X - 130.962962963$$

En este caso sencillo, no es difícil ver que

$$Q \leftarrow \frac{7}{3}X^2 + \frac{65}{9}X + \frac{745}{27} \quad y \quad R \leftarrow \frac{7139}{27}X - \frac{3536}{27}$$

Cuando se trata de polinomios con coeficientes complejos en vez de la función *RuffiniGhay* que utilizar la función siguiente, donde $a_1()$ y $a_2()$ ($p01()$ y $p02()$) son las matrices unidimensionales que contienen las partes reales e imaginarias de los coeficientes del dividendo (divisor), respectivamente.

```

Public Function RuffiniGC(ByRef a1() As Double, ByRef a2() As Double, ByRef p01() As Double, p02() As Double) As Variant

Ejemplo 9: Si

$$A(X) = 1 + 3iX^5 + 1 + iX^4 + 1 + 11iX^3 + 1 - 5iX^2 + 1 - 13iX + 15 - 4i, \text{ y}$$

$$P(X) = X^3 + 1 - 4iX^2 + 1 + 7iX - 1 - 9i$$

, entonces según el código anterior,

$$Q(X) = 1 + 3iX^2 + 1 - 17 + 3iX + 56 - 68i \text{ y } R(X) = 17 + 504iX^2 + 1 - 346 - 759iX + 683 + 432i$$

Ejemplo 10: Si

$$A(X) = 1 + 3iX^5 + 1 + iX^4 + 1 + 11iX^3 + 1 - 5iX^2 + 1 - 13iX + 15 - 4i, \text{ y}$$

$$B(X) = iX^3 + 1 - 3iX^2 + 6X + 13 - 4i$$

, entonces

$$Q(X) = 1 - 2iX^2 + 1 + 16iX - 17 + 227i$$

$$R(X) = 1 - 725 - 1703iX^2 + 1 - 268 - 1487iX - 672 - 3023i$$

Ejemplo 11: Si

$$A(X) = 1 - 5iX^4 + 1 - iX^3 + 1 + 7iX^2 + 1 - 2iX + 3 - 8i, \text{ y } P(X) = 2iX^2 + 1 - 6iX + 7 - i$$

, entonces

$$Q(X) = 1 - 2.5 - iX^2 + 1 - 5.5 - 10.75iX + 16.125 - 56.25i$$

$$R(X) = 1 - 10.125 + 445.75iX - 53.625 + 401.875i$$

La regla general de Ruffini se puede aplicar también a los polinomios con coeficientes duales excepto en el caso cuando el coeficiente director del divisor es un divisor de cero (dual puro). En este caso el código es la siguiente:

```
Public Function RuffiniGD(ByRef a1() As Double, ByRef a2() As Double, ByRef p01() As Double, p02() As Double) As Variant
    Dim g1 As Integer, g2 As Integer, gq As Integer, r() As Double, r1() As Double
    Dim i As Integer, j As Integer, j1 As Integer, res(2) As String, r2() As Double
    Dim b() As Double, x(2) As Double, y(2) As Double, p1() As Double, p2() As Double
    Dim q1() As Double, q2() As Double, b1() As Double, b2() As Double, rr() As Double
    g1 = UBound(a1()): g2 = UBound(p01()): gq = g1 - g2
    ReDim b(gq, 2), b1(gq), b2(gq), r1(g2 - 1), r2(g - 1)
    If p01(1) = 0 Then
        MsgBox "¡La división es imposible!"
        Exit Function
    End If
    'División del divisor con su coeficiente director
    If p01(0) = 1 And p02(0) = 0 Then
        p1() = p01(): p2() = p02()

Ejemplo12 : Si

$A(X) = 4 + 7\epsilon X^5 + 3 + 4\epsilon X^3 + 1 + 5\epsilon X^2 + 3\epsilon X - 5 + 7\epsilon$ y $P(X) = X^2 + 9\epsilon X - 3 + 4\epsilon$, entonces

$$Q(X) = 4 + 7\epsilon X^3 + 8 - 50\epsilon X^2 + 5 + 181\epsilon X - 75 - 700\epsilon \text{ y } R(X) = 25 + 2521\epsilon X - 230 - 1793\epsilon$$

Ejemplo13 : Si $A(X) = 4 - 4\epsilon X^4 + 1 + 2\epsilon X^3 - 5X + \epsilon$ y $P(X) = 4X^2 + 3\epsilon X + 12 - 5\epsilon$

, entonces

$$Q(X) = 0.75 - 0.25\varepsilon X^2 + 0.25 + 1.5625\varepsilon X - 1.75 - 1.625\varepsilon \quad \text{y} \quad R(X) = 2 - 12.25\varepsilon X + 21 + 11.75\varepsilon$$

Se sabe que los ceros enteros de un polinomio real se encuentran entre los divisores del término libre. Luego, el numerador de un cero fraccionario es divisor del término libre y el denominador es divisor del coeficiente director. El código necesario para calcular los ceros enteros y fraccionarios de un polinomio real se basa también en la regla de Ruffini y es la siguiente:

```

Public Function CERuf(ByRef p0() As Double) As String
    Dim i As Integer, res As String, rc As String, gp0 As Integer
    Dim gp As Integer, cr() As Double, j As Integer, p() As Double
    Dim Era As Double, c As Double, c0 As Double, pc0 As Double
    rc = Chr$(13) + Chr$(10)
    gp0 = UBound(p0())
    If p0(gp0) = 0 Then
        res = "0, "
        i = 1
        Do
            If p0(gp0 - i) = 0 Then
                i = i + 1
            Else
                Exit Do
            End If
        Loop
        gp = gp0 - i
        ReDim p(gp)
        For j = 0 To gp: p(j) = p0(j): Next j
    Else
        p() = p0(): gp = gp0
    End If
    cr() = CotasCerosPR2(p())
    If p(gp) = 0 Then res = "0, "
    For i = Int(cr(2) - 1) To Int(cr(1) + 1)
        If i <> 0 Then
            c = p(gp) / i
            If c = Int(c) Then
                c = ValPolR(p(), i)
                If c = 0 Then
                    res = res + Str$(i) + ", "
                End If
            End If
        End If
        Next i
    For j = 2 To Abs(p(0))
        c0 = p(0) / j
        If c0 = Int(c0) Then
            For i = Int(cr(2) - 1) To Int(cr(1) + 1)
                If i <> 0 Then
                    c0 = p(gp) / i
                    If c0 = Int(c0) Then
                        If MaxComDiv2(i, j) = 1 Then
                            c0 = i / j
                            pc0 = ValPolR(p(), c0)
                            Era = Errpa(p(), c0)
                            If pc0 = 0 Or Abs(pc0) < Era Then
                                res = res + Str$(i) + "/" + Str$(j) + ", "

pr(2) = x(1) * a(2) + a(1) * x(2)
ProdNC = pr()
End Function

```

Ejemplo 15: Dado el polinomio

$$P(Z) = Z^4 + (-1+8i)Z^3 + (-16,-7i)Z^2 + (-1+8i)Z - 17 - 7i$$

Según el código anterior resulta que sus ceros enteros de Gauss son: $i - i$, $-1-5i$ y $2-3i$.

En el caso de los polinomios con coeficientes duales enteros la búsqueda de los ceros enteros duales se hace de la misma manera que la búsqueda de los ceros enteros de Gauss de los polinomios con coeficientes enteros de Gauss y el código para estos cálculos es muy parecido:

```

Public Function CEDRUF(ByRef p10() As Double, ByRef p20() As Double, Radio As Double) As String
    Dim i As Long, j As Long, res As String, rc As String, gp0 As Integer, r As Integer

ProdND = pr()
End Function

```

Ejemplo 16: Si se considera el polinomio dual

$$P(X) = X^4 - 6\epsilon X^3 + (-53 - 32\epsilon)X^2 + (-108 - 54\epsilon)X + 160 + 92\epsilon$$

, y se buscan los ceros duales enteros de módulo menor o igual a 25, el código anterior devuelve los ceros duales siguientes:

$$-5+4\epsilon, -4-3\epsilon, \text{ y } 8+5\epsilon.$$

Ejemplo 17: Si $P(X) = X^4 + (-10+5\epsilon)X^3 + (-2-44\epsilon)X^2 + (-32+112\epsilon)X - 64\epsilon$, el código anterior devuelve las siguientes cero duales enteros de módulo menor o igual a 25:

$$-2\epsilon, 2-3\epsilon, 4+k\epsilon \quad k \in \mathbb{Z} \text{ y } |k| \leq 24$$

Si el polinomio

$$P(X) = a_0 X^n + a_1 X^{n-1} + \cdots + a_{n-1} X + a_n \quad (12)$$

, tiene coeficientes reales y A es una matriz cuadrada de orden m con elementos reales, entonces el valor del polinomio P para la matriz cuadrada A se define por la igualdad:

$$P(A) = a_0 A^n + a_1 A^{n-1} + \cdots + a_{n-1} A + a_n I$$

, donde I es la matriz cuadrada unidad de orden m .

La matriz $P(A)$ podría ser calculada hallando primero las potencias A^2, \dots, A^n de la matriz A y sumando luego las matrices

$$a_0 A^n, a_1 A^{n-1}, \dots, a_{n-1} A, a_n I$$

Efectuando los cálculos de ésta manera, el volumen de los cálculos es bastante elevado. Sin embargo, observando que

$$P(A) = (\cdots(((a_0 A + a_1 I)A + a_2 I)A + a_3 I) + \cdots + a_{n-1} I)A + a_n I \quad (13)$$

, habrá muchísimo menos cálculo. Es evidente que este valor de $P(A)$ es igual al resto de la división del polinomio

$$P(A) = a_0 I + \cdots + a_{n-1} A + a_n I \quad (14)$$

, con coeficientes matriciales, entre $X - A$. En efecto,

	$a_0 I$	$a_1 I$	\dots	$a_k I$	$a_{k+1} I$	\dots	$a_{n-1} I$	$a_n I$
A		$a_0 A$	\dots			\dots		
	$q_0 = a_0 I$	$q_1 = a_0 A + a_1 I$	\dots	q_k	q_{k+1}	\dots	q_{n-1}	R

, donde

$$q_k = (\cdots(((a_0 A + a_1 I)A + a_2 I)A + a_3 I) + \cdots + a_{k-1} I)A + a_k I$$

$$q_{k+1} = q_k A + a_{k+1} I = (\cdots(((a_0 A + a_1 I)A + a_2 I)A + a_3 I) + \cdots + a_k I)A + a_{k+1} I$$

$$R = q_{n-1} A + a_n I = (\cdots(((a_0 A + a_1 I)A + a_2 I)A + a_3 I) + \cdots + a_{n-1} I)A + a_n I = P(A)$$

Utilizando la fórmula (13) para calcular el valor de $P(A)$, el código es la siguiente:

```
Public Function VMP(ByRef p() As Double, ByRef m() As Double) As Variant
```

```
Dim i As Integer, j As Integer, k As Integer
```

```
Dim n As Integer, g As Integer
```

```

g = UBound(p()): n = UBound(m())
ReDim a(n, n)
a() = MultNum(p(0), m())
For k = 1 To g
    For i = 1 To n
        a(i, i) = a(i, i) + p(k)
    Next i
    If k <> g Then
        a() = MultMatCuadradas(a(), m())
    End If
Next k
VMP = a()
End Function
' -----
Public Function MultMatCuadradas(ByRef a() As Double, ByRef b() As Double) As Variant
    Dim i As Integer, j As Integer, k As Integer

    Dim i As Integer, j As Integer, n As Integer, z() As Double
    n = UBound(d())
    ReDim z(n, n)
    For i = 1 To n
        For j = 1 To n
            z(i, j) = nu * d(i, j)
        Next j
    Next i
    MultNum = z()
End Function
' -----
Public Function VerMatriz(ByRef x() As Double) As Variant
    Dim i As Integer, j As Integer, n As Integer, mt As String
    n = UBound(x())
    For i = 1 To n
        mt = mt + " Fila" + Str$(i) + ": "
        For j = 1 To n
            mt = mt + Str$(x(i, j))
            If j < n Then
                mt = mt + " ; "
            End If
        Next j
        mt = mt + rc + " " + rc
    Next i
    VerMatriz = mt
End Function

```

Si el polinomio (12) y la matriz cuadrada A son complejos, para calcular el valor del polinomio para la matriz A se procede de manera análoga al caso real. En este caso el código es la siguiente:

```

Public Function VMPC(ByRef a0() As Double, ByRef p() As Double) As Variant
    Dim i As Integer, j As Integer, k As Integer, u As Integer
    Dim n As Integer, g As Integer
    n = UBound(a0(), 1): g = UBound(p(), 1)
    ReDim a(n, n, 2)

```

```

' Esquema de Riffini
For i = 1 To n
    For j = 1 To n
        a(i, j, 1) = p(0, 1) * a0(i, j, 1) - p(0, 2) * a0(i, j, 2)
        a(i, j, 2) = p(0, 1) * a0(i, j, 2) + p(0, 2) * a0(i, j, 1)
    Next j
Next i
For k = 1 To g
    For i = 1 To n

                End If
            End If
        End If
        nc = nc + " e"
    End If
    If nc = "" Then nc = "0"
    FormatoDual = nc
End Function

```

Ejemplo 19: Si $P(X) = 2X^3 - 3X^2 + 5X - 7$ y $A = \begin{pmatrix} -1+\varepsilon & 4-3\varepsilon \\ 2+3\varepsilon & 1+5\varepsilon \end{pmatrix}$, entonces

$$P(A) = \begin{pmatrix} -57+99\varepsilon & 92-61\varepsilon \\ 46+73\varepsilon & -71+135\varepsilon \end{pmatrix}.$$

Naturalmente, en este ejemplo los coeficientes del polinomio son reales pero se han introducido como números duales con la parte dual nula.
